# Agenda

- 1. Classification
- 2. Binary Classification
- 3. Decision Boundary
- 4. Cost Function
- 5. Multiclass Classification
- 6. Regularization
- 7. Hands on Scikit

# Classification Problem

#### SPAM CLASSIFIER MODEL

Student 2 Test: 3/10 🔀 Grades: 4/10

Student 3 Test: 7/10 😰 Grades: 6/10

**NOT SPAM** 

SPAM

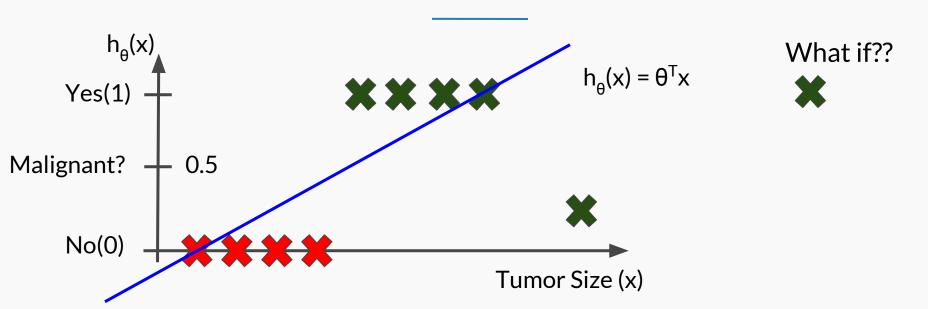

# Binary Classification Problem

- Email = {spam, not spam}
- Medical model = {healthy, sick}
- Fraudulent operation = {yes, not}
- Academic acceptance = {success, fail}
- Movie review = {good, bad}

$$Y \in \{0,1\}$$
 0: negative class 1: positive class

# Binary Classification Problem (observation #1)

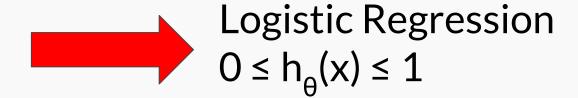

Threshold classifier output as  $h_{\theta}(x)$ :

- If  $h_{\theta}(x) \ge 0.5$ , predict y = 1If  $h_{\theta}(x) < 0.5$ , predict y = 0

# Binary Classification Problem (observation #2)

- Y assume only two values: 0 or 1.
- In linear case,  $h_{\theta}(x) > 1$  and  $h_{\theta}(x) < 0$  can occur.

# Logistic Regression - Hypothesis Representation

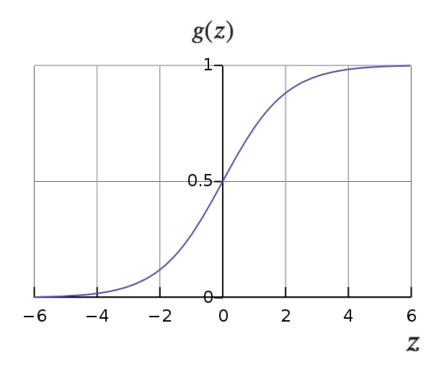

Target  $\rightarrow 0 \le h_{\theta}(x) \le 1$ 

$$h_{\theta}(x) = \theta^T x$$
 (doesn't work)

$$h_{ heta}(x) = g(z)$$
 ,where  $z = \theta^T x$ 

$$g(z)=rac{1}{1+e^{-z}}$$

Sigmoid function or logistic function

#### Suppose:

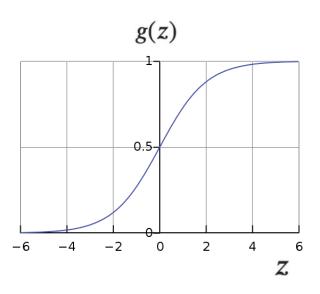

Predict y = 1 if  $h_{\theta}(x) \ge 0.5$ 

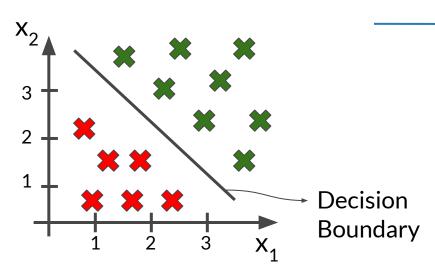

$$g(z) \ge 0.5$$
 when  $z \ge 0$ 

#### Suppose:

Predict y = 0 if  $h_{\theta}(x) < 0.5$ 

$$g(z) < 0.5$$
 when  $z < 0$ 

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$$

$$\theta = \begin{bmatrix} -3 \\ 1 \\ 1 \end{bmatrix}$$

$$z = -3 + x_1 + x_2$$

#### Suppose:

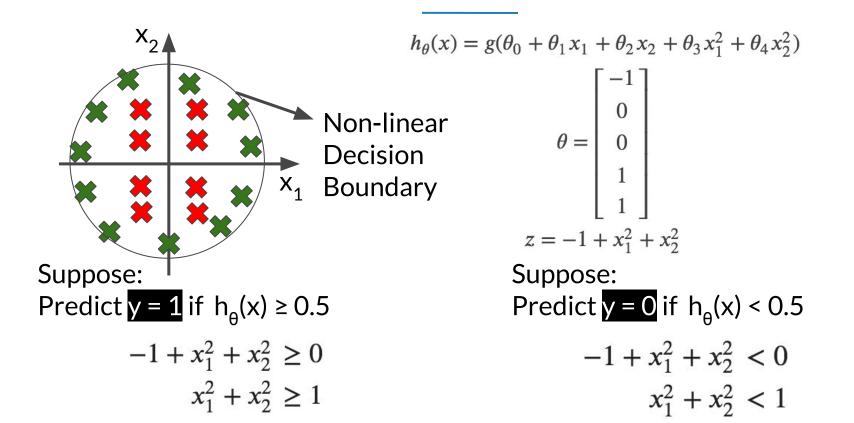

Predict y = 1 if  $h_{\theta}(x) \ge 0.5$ 

$$-3 + x_1 + x_2 \ge 0$$
  
$$x_1 + x_2 \ge 3$$

Predict y = 0 if  $h_{\theta}(x) < 0.5$ 

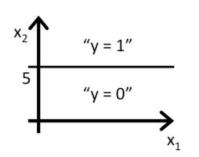

$$-3 + x_1 + x_2 < 0$$
  
$$x_1 + x_2 < 3$$

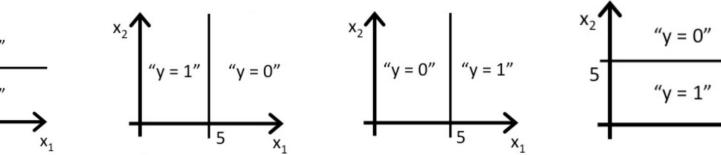

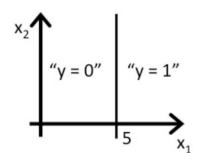

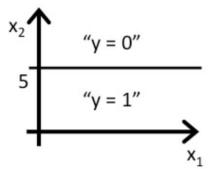

Consider logistic regression with two features  $x_1$  and  $x_2$ . Suppose  $\Theta_0 = 5$ ,  $\Theta_1 = -1$  and  $\Theta_2 = 0$ , so that  $h_{\Theta}(x) = g(5 - x_1)$ .

Which of these shows the decision boundary of  $h_{\Theta}(x)$ ?

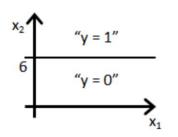

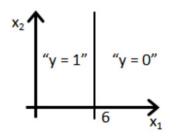

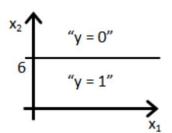

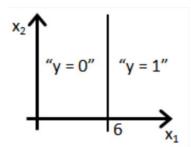

Consider logistic regression with two features  $x_1$  and  $x_2$ . Suppose  $\Theta_0 = 6$ ,  $\Theta_1 = 0$  and  $\Theta_2 = -1$ , so that  $h_{\Theta}(x) = g(\Theta_0 + \Theta_1 x_1 + \Theta_2 x_2)$ .

Which of these shows the decision boundary of  $h_{\Theta}(x)$ ?

Suppose that you have trained a logistic regression classifier, and it outputs on a new example x a prediction  $h_{\theta}(x)$  = 0.4. This means (check all that apply):

Our estimate for  $P(y = 0|x; \theta)$  is 0.4.

Our estimate for  $P(y = 0|x; \theta)$  is 0.6.

Our estimate for  $P(y = 1|x; \theta)$  is 0.4.

Our estimate for  $P(y = 1|x; \theta)$  is 0.6.

# RECAP

f(x) cost function

# Training Set: $\{(x^1, y^1), (x^2, y^2), ..., (x^m, y^m)\}$ m examples

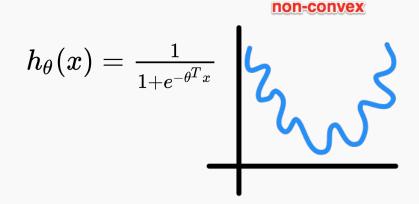

$$x \in egin{bmatrix} x_0 \ x_1 \ dots \ x_n \end{bmatrix}, x_0 = 1, y \in \{0,1\}$$
  $h_ heta(x) = rac{1}{1 + e^{- heta^T x}}$ 

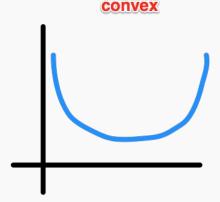

How to fit the parameter  $\theta$ ?

### **Cost Function**

$$J( heta) = rac{1}{m} \sum_{i=1}^m rac{1}{2} (h_ heta(x^i) - y^i)^2 \qquad cost(h_ heta(x), y)$$

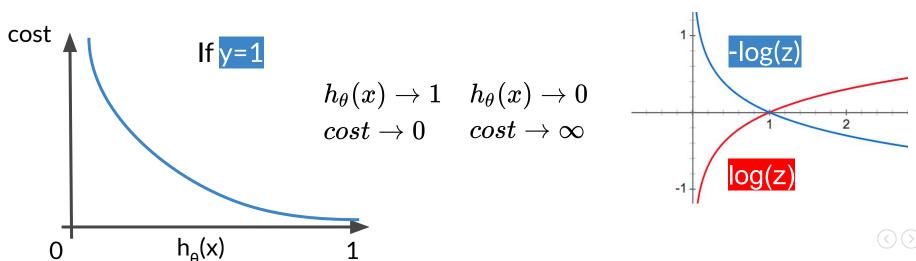

# Logistic Regression Cost Function

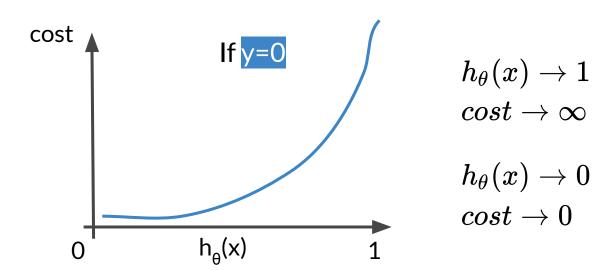

$$cost(h_{ heta}(x),y) = egin{cases} -log(h_{ heta}(x)) & ext{if y=1} \ -log(1-h_{ heta}(x)) & ext{if y=0} \end{cases}$$

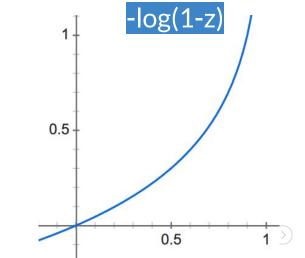

# Logistic Regression Cost Function

$$cost(h_{ heta}(x),y) = egin{cases} -log(h_{ heta}(x)) & ext{if y=1} \ -log(1-h_{ heta}(x)) & ext{if y=0} \end{cases}$$

# Simplified Cost Function & Gradient Descent

# Logistic Regression Cost Function

$$egin{aligned} cost(h_{ heta}(x),y) &= egin{cases} -log(h_{ heta}(x)) & ext{if y=1} \ -log(1-h_{ heta}(x)) & ext{if y=0} \end{cases} \ cost(h_{ heta}(x),y) &= -y \ log(h_{ heta}(x)) - (1-y) log(1-h_{ heta}(x)) \end{aligned}$$

 $J( heta) = -rac{1}{m} \sum [y^{(i)} \log(h_{ heta}(x^{(i)})) + (1-y^{(i)}) \log(1-h_{ heta}(x^{(i)}))]$ 

# **Cost Function - Vectorized Implementation**

$$J( heta) = -rac{1}{m} \sum_{i=1}^m [y^{(i)} \log(h_ heta(x^{(i)})) + (1-y^{(i)}) \log(1-h_ heta(x^{(i)}))]$$

$$\theta = \begin{bmatrix} \theta_0 \\ \theta_1 \\ \vdots \\ \theta_k \end{bmatrix} \qquad h = g(X\theta)$$

$$I(\theta) = \frac{1}{m} \cdot \left( -y^T \log(h) - (1 - y)^T \log(1 - h) \right)$$

$$[1;m] \times [m;1] = \text{scalar}$$

### General Form of Gradient Descent

# Repeat { $\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta)$

**Vectorized Implementation** 

$$heta := heta - rac{lpha}{m} X^T (g(X heta) - ec{y})$$

Repeat {

$$\theta_j := \theta_j - \frac{\alpha}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

# Multiclass Classification: One vs All

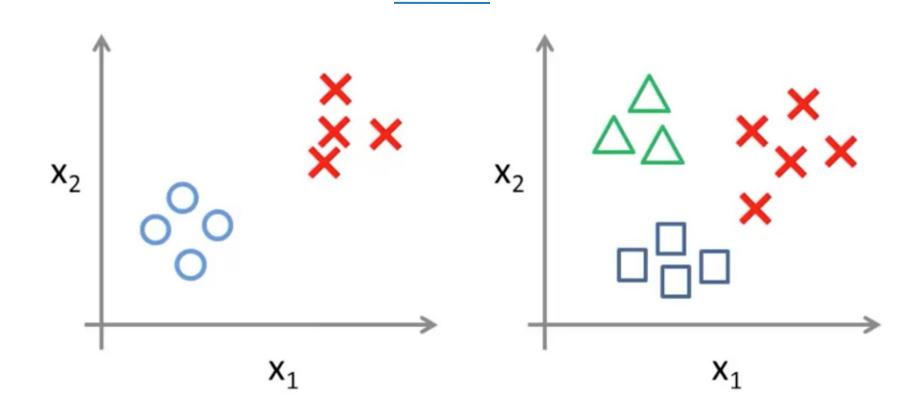

## **Multiclass Classification**

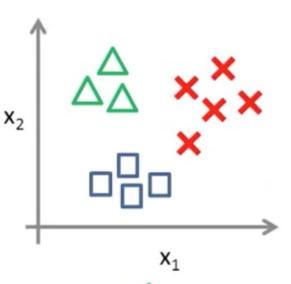

- Email foldering/tagging: work, ad, family, friends, hobby
- Medical diagrams: not ill, cold, flu
- Weather: sunny, cloudy, rain, snow

# Binary vs Multiclass Classification

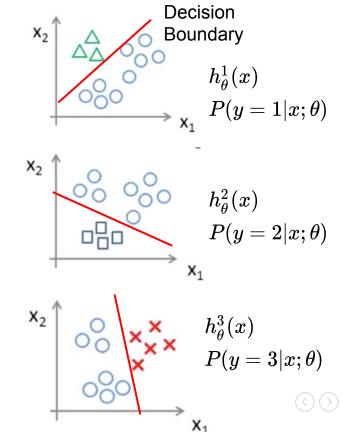

# Multiclass Classification (One vs All)

Class 1: △ Class 2: □

Class 3: X

# Multiclass Classification (One vs All)

Train a logistic regression classifier  $h_{\theta}^{(i)}(x)$  for each class i:

$$h^i_ heta(x) = P(y=i|x; heta)$$

On a new input x, to make a prediction, pick the class i that maximizes:

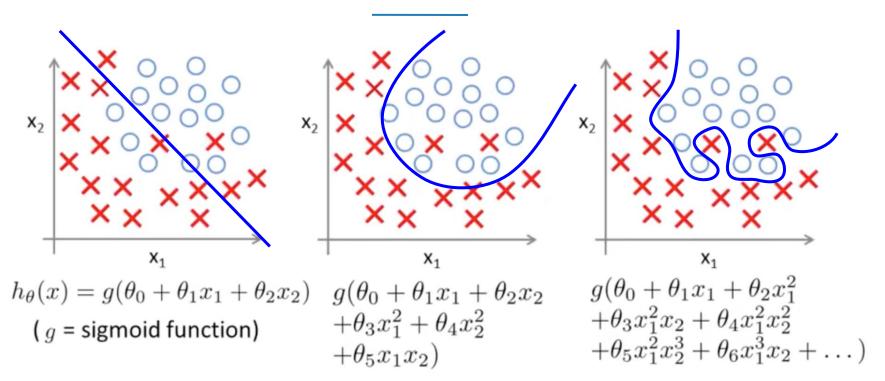

$$\max_{i} h_{\theta}^{(i)}(x)$$

# overfitting problem

# Logistic Regression

Underfit

Overfit

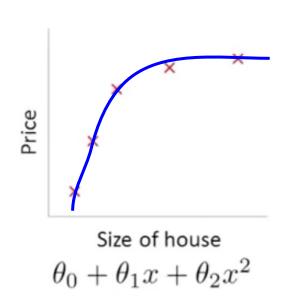

# Addressing Overfitting

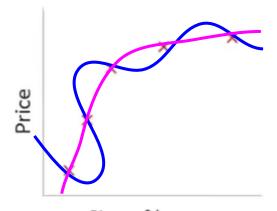

- 1. Reduce number of features
  - a. Manually select which feature to keep
- 2. Regularization
  - a. Keep all the features, but reduce magnitude/values of parameters  $\Theta_i$
  - b. Works well when we have a lot of features, each of which contributes a bit to predicting y.

# Intuition - Regularized Linear Regression

$$min_{ heta} \; rac{1}{2m} \; \sum_{i=1}^m (h_{ heta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n heta_j^2$$

Regularization Parameter

$$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

Suppose we penalize and make  $\Theta_3$  and  $\Theta_4$  very small

$$min_{ heta} \; rac{1}{2m} \sum_{i=1}^m (h_{ heta}(x^{(i)}) - y^{(i)})^2 + 1000 \cdot heta_3^2 + 1000 \cdot heta_4^2$$

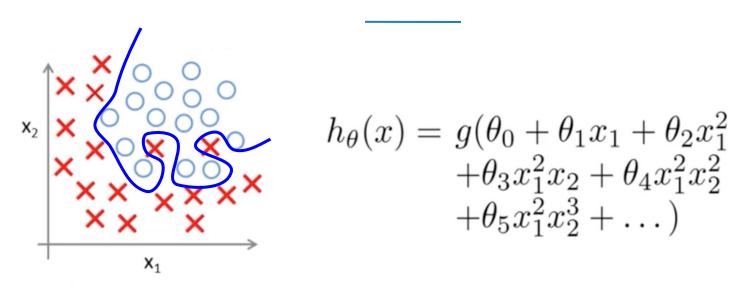

### Intuition - Gradient Descent

Repeat { 
$$\theta_0 := \theta_0 - \alpha \, \frac{1}{m} \, \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_0^{(i)}$$
 
$$\theta_j := \theta_j - \alpha \, \left[ \left( \frac{1}{m} \, \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)} \right) + \frac{\lambda}{m} \, \theta_j \right]$$
  $j \in \{1, 2...n\}$  }

 $heta_{i} := heta_{i}(1 - lpha rac{\lambda}{m}) - lpha rac{1}{m} \sum_{i=1}^{m} (h_{ heta}(x^{(i)}) - y^{(i)}) x_{i}^{(i)}$ 

# Intuition - Regularized Logistic Regression

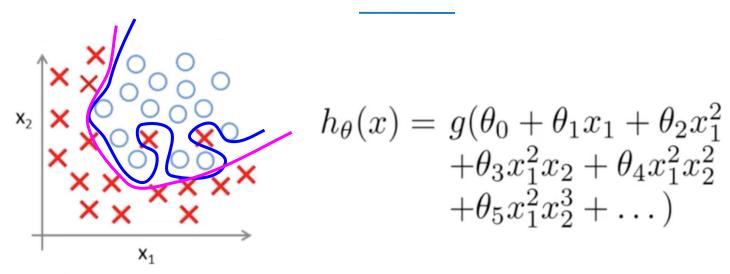

#### Cost function:

$$J(\theta) = -\left[\frac{1}{m} \sum_{i=1}^{m} y^{(i)} \log h_{\theta}(x^{(i)}) + (1 - y^{(i)}) \log (1 - h_{\theta}(x^{(i)}))\right]$$

# Intuition - Regularized Logistic Regression

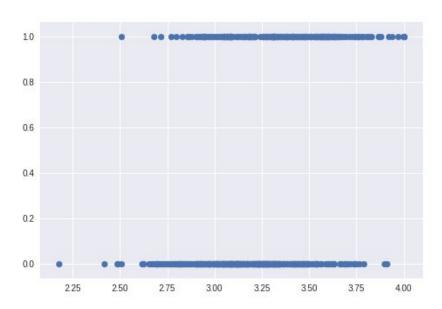

Cost function:

$$J( heta) = -rac{1}{m} \sum_{i=1}^m \left[ y^{(i)} \; \log(h_ heta(x^{(i)})) + (1-y^{(i)}) \; \log(1-h_ heta(x^{(i)})) 
ight] + \left( rac{\lambda}{2m} \sum_{j=1}^n heta_j^2 
ight)$$
